

Proposed Solution

Date	05 July 2026
Team ID	
Project Name	Credit Card Approval Prediction
Maximum Marks	4 Marks

Problem Statement	Manual credit card approval review is slow, inconsistent, and error-prone, leaving both banks and applicants without a fast, reliable way to gauge approval likelihood.
Idea / Solution Description	Build a machine learning system that trains multiple classification algorithms (Logistic Regression, Random Forest, XGBoost, Decision Tree) on historical applicant data, selects the best-performing model, and serves predictions through a Flask web application, deployed on the cloud via IBM Watson Machine Learning.
Novelty / Uniqueness	Combines feature engineering (e.g., converting multi-class payment status codes into binary risk labels) with a comparative multi-model approach, and offers both single-applicant and batch-screening workflows in one platform.
Social Impact / Value Proposition	Reduces processing time for banks, cuts human error and bias in decisions, and gives applicants instant clarity on eligibility — improving financial inclusion and transparency.
Business Model (Revenue Model)	Licensed as a SaaS module for banks and NBFCs (subscription/per-prediction pricing), or integrated as an add-on service within existing core banking software.
Scalability of the Solution	Cloud deployment via IBM Watson Machine Learning allows horizontal scaling to handle spikes in application volume, and the model can be retrained periodically as more data becomes available.

Project: Credit Card Approval Prediction
